After all these posts about resonance, I thought it would be good to have a post summarizing what's been discussed so far. One of the key skills in analyzing the reactivity of a molecule is to be able to figure out where the electrons are. As I wrote here, if we're dealing with single bonds, it's a relatively straightforward matter of figuring out the differences in electronegativities. Nucleophilic aromatic substitution ( $S_NAr$ ) is one of the most widely applied reaction classes in pharmaceutical and chemical research, providing a broadly useful platform for the modification of ... In chemistry, resonance is a way of describing bonding in certain molecules or ions by the combination of several contributing structures (or forms, also variously known as resonance structures or canonical structures) into a resonance hybrid (or hybrid structure) in valence bond theory. It has particular value for describing delocalized electrons within certain molecules or polyatomic ions ...
